There have been known various methods for embossing products such as paper, for example, on the surfaces thereof. For instance, according to a first method, a plastically deformable thermoplastic resin is applied to the surface of a product, and the plastically deformable resin is heated to melt the same, and thereupon, the product is shaped to have a desired three-dimensionally embossed image thereon. According to a second method, a thermoplastic resin is heated to soften the same, and the product is shaped by a desired three-dimensionally embossed image formed on a male embossing die, while the same is in the softened condition. Where such an image has been formed on the surface of paper, however, it is practically impossible to get the desired image onto the surface of paper, because a predetermined uniform thickness cannot be kept on the paper unless the thickness of paper is uniform at all points. Also, although a conventional embossing is carried out at one point in a very short period of time, a conventional embossing apparatus has an advantage that the shape of an embossed product can be examined at any time, because the product can be easily removed from an embossing roll. However, such a single-point emb
